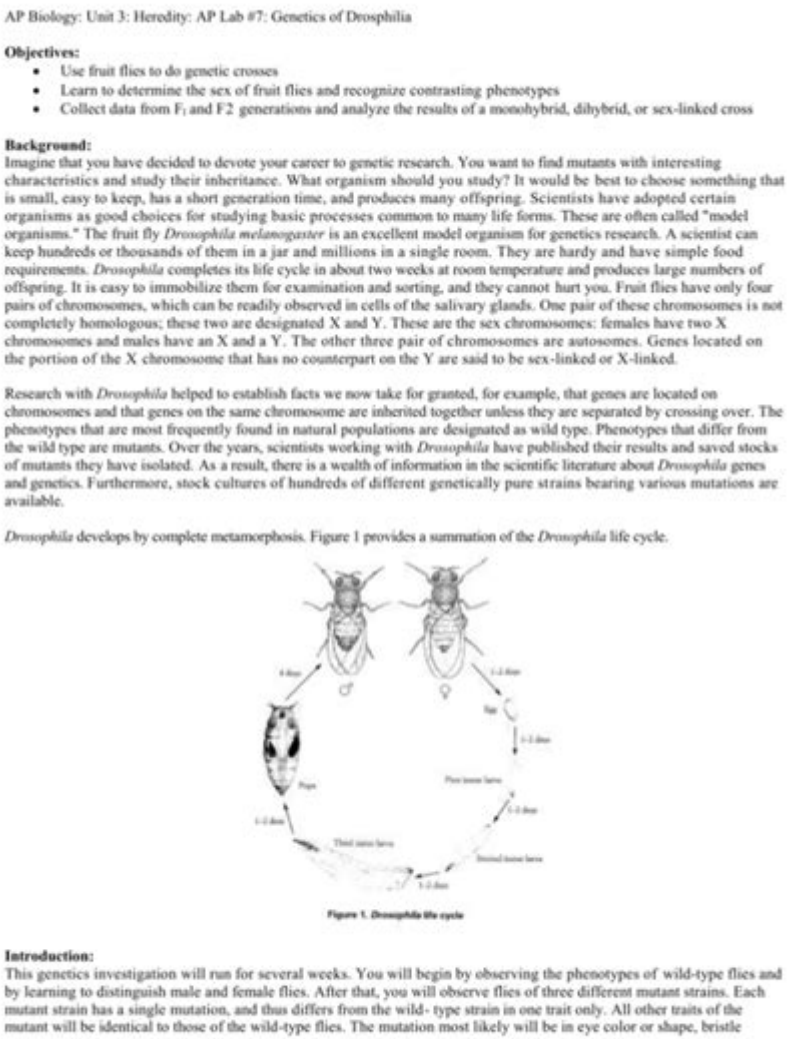
Ap Biology Lab 7 Genetics Of Drosophila Answers



AP Biology: Unit 3: Heredity: AP Lab #7: Genetics of Drosphilia

Objectives:

- Use fruit flies to do genetic crosses
- Learn to determine the sex of fruit flies and recognize contrasting phenotypes
- Collect data from F_1 and F2 generations and analyze the results of a monohybrid, dihybrid, or sex-linked cross

Background:
Imagine that you have decided to devote your career to genetic research. You want to find mutants with interesting characteristics and study their inheritance. What organism should you study? It would be best to choose something that is small, easy to keep, has a short generation time, and produces many offspring. Scientists have adopted certain organisms as good choices for studying basic processes common to many life forms. These are often called "model organisms." The fruit fly *Drosophila melanogaster* is an excellent model organism for genetics research. A scientist can keep hundreds or thousands of them in a jar and millions in a single room. They are hardy and have simple food requirements. *Drosophila* completes its life cycle in about two weeks at room temperature and produces large numbers of offspring. It is easy to immobilize them for examination and sorting, and they cannot hurt you. Fruit flies have only four pairs of chromosomes, which can be readily observed in cells of the salivary glands. One pair of these chromosomes is not completely homologous; these two are designated X and Y. These are the sex chromosomes: females have two X chromosomes and males have an X and a Y. The other three pair of chromosomes are autosomes. Genes located on the portion of the X chromosome that has no counterpart on the Y are said to be sex-linked or X-linked.

Research with *Drosophila* helped to establish facts we now take for granted, for example, that genes are located on chromosomes and that genes on the same chromosome are inherited together unless they are separated by crossing over. The phenotypes that are most frequently found in natural populations are designated as wild type. Phenotypes that differ from the wild type are mutants. Over the years, scientists working with *Drosophila* have published their results and saved stocks of mutants they have isolated. As a result, there is a wealth of information in the scientific literature about *Drosophila* genes and genetics. Furthermore, stock cultures of hundreds of different genetically pure strains bearing various mutations are available.

Drosophila develops by complete metamorphosis. Figure 1 provides a summation of the *Drosophila* life cycle.

Introduction:
This genetics investigation will run for several weeks. You will begin by observing the phenotypes of wild-type flies and by learning to distinguish male and female flies. After that, you will observe flies of three different mutant strains. Each mutant strain has a single mutation, and thus differs from the wild- type strain in one trait only. All other traits of the mutant will be identical to those of the wild-type flies. The mutation most likely will be in eye color or shape, bristle

AP Biology Lab 7 Genetics of Drosophila Answers is a crucial component of the Advanced Placement Biology curriculum. This lab focuses on understanding the principles of genetics through the study of fruit flies, Drosophila melanogaster. Drosophila is an ideal organism for genetic studies due to its short life cycle, ease of culture, and well-mapped genome. In this article, we will explore the fundamental concepts of the lab, the methodology used, and how to interpret the results, as well as provide insights into the genetic crosses performed and the expected outcomes.

Understanding Drosophila Genetics

Drosophila melanogaster has been a cornerstone of genetic research since the early 20th century. The organism exhibits a variety of traits that can be easily observed and quantified, making it an excellent model organism for studying inheritance patterns.

Key Concepts in Genetics

1. Genes and Alleles:
- A gene is a segment of DNA that encodes a trait, while an allele is a variant form of a gene. For example, the gene for eye color in Drosophila has different alleles that produce red or white eyes.

2. Genotype and Phenotype:
- The genotype refers to the genetic makeup of an organism (e.g., homozygous or heterozygous), while the phenotype is the observable characteristic (e.g., red or white eyes).

3. Mendelian Inheritance:
- Gregor Mendel’s principles of segregation and independent assortment govern inheritance patterns in Drosophila. The lab explores these principles through specific genetic crosses.

4. Linkage and Recombination:
- Genes located close together on the same chromosome tend to be inherited together, a phenomenon known as linkage. Recombination can occur during meiosis, leading to genetic variation.

Objectives of the Lab

The primary objectives of AP Biology Lab 7 include:

- To understand the principles of Mendelian genetics through the use of Drosophila.
- To perform genetic crosses and analyze the resulting offspring.
- To determine the inheritance patterns of specific traits.
- To calculate and interpret phenotypic ratios and understand deviations from expected outcomes.

Materials and Methods

Materials Needed

- Drosophila cultures (various phenotypes)

- Vials for breeding and rearing flies
- Yeast for food
- Dissection microscope
- Brushes for transferring flies
- Staining materials (if necessary for observing traits)
- Data sheets for recording observations

Procedure Overview

1. Preparation of Cultures:
- Start by establishing cultures of Drosophila with known phenotypes. Common traits studied include eye color (red vs. white) and wing shape (normal vs. vestigial).

2. Crossing Drosophila:
- Perform genetic crosses by transferring males and females of different phenotypes into vials. Ensure to label each vial with the phenotype and date.

3. Collecting Offspring:
- After a few days, observe the offspring. Use a microscope to identify and count individuals based on the traits of interest.

4. Data Analysis:
- Record the number of each phenotype observed. Calculate the expected ratios based on Mendelian inheritance principles.

5. Performing Test Crosses:
- Conduct test crosses to determine the genotype of individuals with dominant phenotypes. This involves crossing the unknown genotype with a homozygous recessive individual.

Expected Results and Analysis

Phenotypic Ratios

In a typical monohybrid cross involving a trait like eye color, the expected phenotypic ratio in the F2 generation is usually 3:1 (dominant:recessive). In a dihybrid cross involving two traits, the expected ratio is 9:3:3:1.

- Example 1: Red eyes (R) are dominant over white eyes (r).
- F1 Generation: All offspring have red eyes (Rr).
- F2 Generation: Expected ratio is 3 red (RR or Rr) to 1 white (rr).

- Example 2: Normal wings (N) are dominant over vestigial wings (n).
- F1 Generation: All offspring have normal wings (Nn).
- F2 Generation: Expected ratio is 3 normal (NN or Nn) to 1 vestigial (nn).

Calculating Phenotypic Ratios

To analyze the data, students must:

1. Count the Offspring: Record the number of each phenotype observed.
2. Calculate Ratios: Use the formula:
- Ratio = (Number of Dominant Phenotype) : (Number of Recessive Phenotype)
3. Compare to Expected Ratios: Determine if the observed ratios conform to Mendelian predictions.

Chi-Square Analysis

To assess the goodness of fit between observed and expected ratios, a chi-square test can be conducted. The formula is:

$$
\chi^2 = \sum \frac{(O - E)^2}{E}
$$

Where:
- O = observed frequency
- E = expected frequency

Determine the degrees of freedom and use a chi-square table to assess statistical significance.

Common Genetic Crosses in Drosophila

Understanding common genetic crosses can enhance comprehension of inheritance patterns:

1. Monohybrid Cross:
- Examines the inheritance of a single trait.
- Example: Cross between red-eyed and white-eyed flies.

2. Dihybrid Cross:
- Investigates the inheritance of two traits simultaneously.
- Example: Cross between flies with normal wings and red eyes versus flies with vestigial wings and white eyes.

3. Test Cross:
- Used to determine the genotype of an individual with a dominant phenotype.
- Involves crossing with a homozygous recessive.
