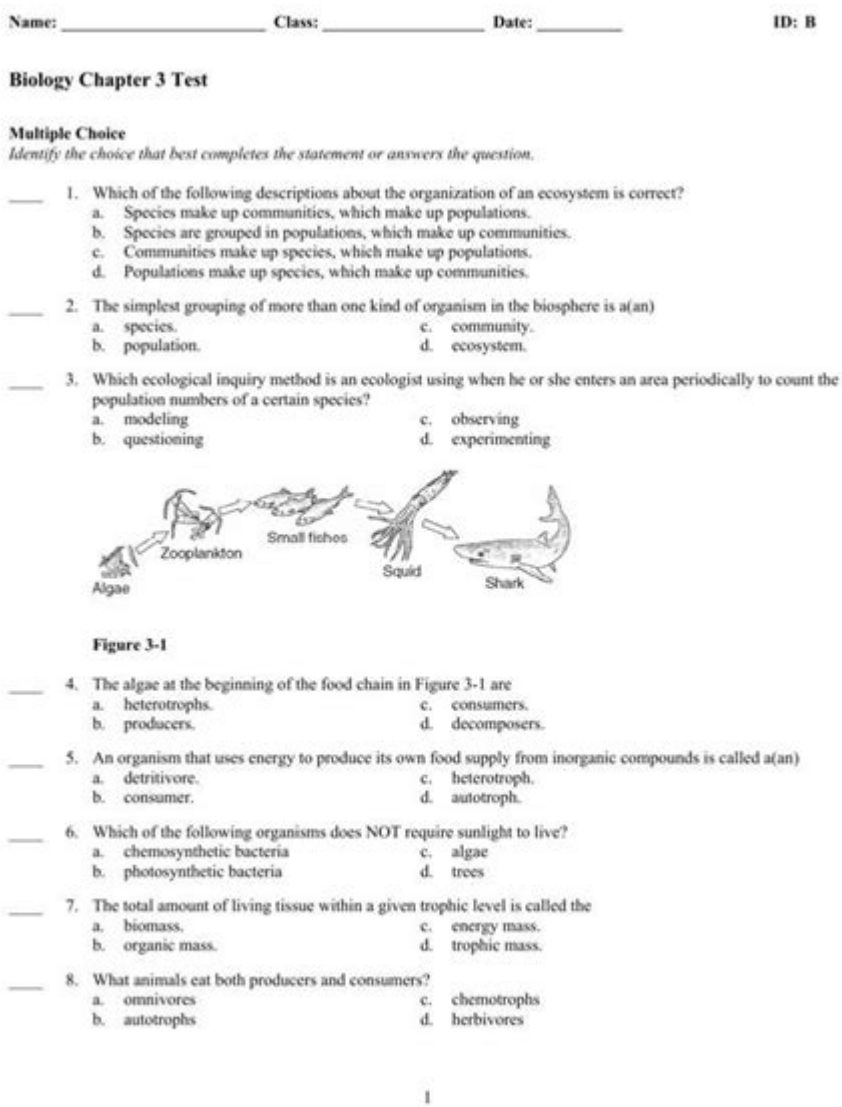
Ap Biology Chapter 17



Name: _____ Class: _____ Date: _____ ID: B

Biology Chapter 3 Test

Multiple Choice
Identify the choice that best completes the statement or answers the question.

___ 1. Which of the following descriptions about the organization of an ecosystem is correct?
a. Species make up communities, which make up populations.
b. Species are grouped in populations, which make up communities.
c. Communities make up species, which make up populations.
d. Populations make up species, which make up communities.

___ 2. The simplest grouping of more than one kind of organism in the biosphere is a(an)
a. species.
b. population.
c. community.
d. ecosystem.

___ 3. Which ecological inquiry method is an ecologist using when he or she enters an area periodically to count the population numbers of a certain species?
a. modeling
b. questioning
c. observing
d. experimenting

Zooplankton
Small fishes
Squid
Shark
Algae

Figure 3-1

___ 4. The algae at the beginning of the food chain in Figure 3-1 are
a. heterotrophs.
b. producers.
c. consumers.
d. decomposers.

___ 5. An organism that uses energy to produce its own food supply from inorganic compounds is called a(an)
a. detritivore.
b. consumer.
c. heterotroph.
d. autotroph.

___ 6. Which of the following organisms does NOT require sunlight to live?
a. chemosynthetic bacteria
b. photosynthetic bacteria
c. algae
d. trees

___ 7. The total amount of living tissue within a given trophic level is called the
a. biomass.
b. organic mass.
c. energy mass.
d. trophic mass.

___ 8. What animals eat both producers and consumers?
a. omnivores
b. autotrophs
c. chemotrophs
d. herbivores

1

AP Biology Chapter 17 delves into the fascinating world of gene expression and regulation, a critical aspect of molecular biology that explains how genes dictate the functional characteristics of living organisms. This chapter focuses on the central dogma of molecular biology, which describes the flow of genetic information from DNA to RNA to protein. Understanding these processes is essential for students preparing for the AP Biology exam and for anyone interested in the molecular mechanisms that underpin life.

The Central Dogma of Molecular Biology

At the core of AP Biology Chapter 17 is the central dogma, which outlines the two main processes involved in gene expression: transcription and

translation.

Transcription

Transcription is the first step in the process of gene expression, where a specific segment of DNA is copied into RNA. Here are the key points regarding transcription:

- **Initiation:** RNA polymerase binds to the promoter region of a gene, unwinding the DNA strands and preparing for RNA synthesis.
- **Elongation:** RNA polymerase moves along the DNA template, synthesizing a complementary RNA strand by adding RNA nucleotides.
- **Termination:** Transcription ends when RNA polymerase reaches a termination sequence, releasing the newly formed mRNA strand.

Post-Transcriptional Modifications

Before the mRNA can be translated into protein, it undergoes several modifications in eukaryotic cells:

- **5' Capping:** A modified guanine nucleotide is added to the 5' end of the mRNA, which protects it from degradation and aids in ribosome binding.
- **Polyadenylation:** A tail of adenine nucleotides (poly-A tail) is added to the 3' end, enhancing mRNA stability and export from the nucleus.
- **Splicing:** Introns (non-coding regions) are removed, and exons (coding regions) are joined together, creating a mature mRNA molecule.

Translation

Translation is the process by which the mRNA sequence is decoded to produce a polypeptide chain, which will fold into a functional protein.

Ribosomes and tRNA

Ribosomes play a crucial role in translation, serving as the site where mRNA and transfer RNA (tRNA) come together. The tRNA molecules bring specific amino acids to the ribosome, matching their anticodon to the corresponding codon on the mRNA.

The Stages of Translation

Translation can be broken down into three main stages:

1. **Initiation:** The small ribosomal subunit binds to the mRNA at the start codon (AUG), and the initiator tRNA carrying methionine (the first amino acid) binds to this codon.

2. **Elongation:** The ribosome moves along the mRNA, facilitating the binding of tRNA to the A site, forming peptide bonds between amino acids, and shifting the ribosome along the mRNA strand.

3. **Termination:** The process ends when a stop codon (UAA, UAG, or UGA) is reached. Release factors promote the release of the newly synthesized polypeptide and the disassembly of the ribosomal complex.

Gene Regulation

Understanding gene regulation is crucial as it determines how and when genes are expressed, allowing organisms to respond to their internal and external environments.

Types of Gene Regulation

Gene regulation can occur at multiple levels, including:

- **Transcriptional Regulation:** Factors such as transcription factors enhance or inhibit the binding of RNA polymerase to the promoter, thereby controlling the initiation of transcription.

- **Post-Transcriptional Regulation:** This includes mRNA stability, splicing variations, and the regulation of mRNA translation by microRNAs.

- **Translational Regulation:** The availability of tRNA and ribosomes can

influence the rate of protein synthesis, affecting how much protein is produced from a given mRNA transcript.

- **Post-Translational Modification:** After translation, proteins may undergo various modifications (e.g., phosphorylation, methylation) that affect their activity and function.

Examples of Gene Regulation

In AP Biology Chapter 17, several examples illustrate the complexity of gene regulation:

- **Lac Operon:** In E. coli, the lac operon is an example of inducible regulation, where the presence of lactose activates the operon to produce enzymes for lactose metabolism.
- **Trp Operon:** Conversely, the trp operon is a repressible system that inhibits the production of tryptophan when it is abundant.
- **Enhancers and Silencers:** These are DNA elements that can increase (enhancers) or decrease (silencers) transcription from a distance, demonstrating the intricate regulation of gene expression.

Conclusion

AP Biology Chapter 17 provides a comprehensive overview of gene expression and regulation, emphasizing the importance of transcription and translation as well as the mechanisms that control them. Mastering these concepts is vital for students not only in preparation for their exams but also in building a foundation for understanding more complex biological processes. From the central dogma to gene regulation, the principles covered in this chapter highlight the dynamic and intricate nature of life at the molecular level. By grasping these fundamental concepts, students can better appreciate the underlying biological principles that govern all living organisms.

Frequently Asked Questions

What is the main focus of AP Biology Chapter 17?

AP Biology Chapter 17 primarily focuses on the processes of gene expression,

including transcription and translation, and how these processes contribute to the phenotype of organisms.

How does the structure of RNA differ from that of DNA?

RNA is typically single-stranded and contains ribose as its sugar, while DNA is double-stranded and contains deoxyribose. Additionally, RNA uses uracil in place of thymine, which is found in DNA.

What role do ribosomes play in protein synthesis as described in Chapter 17?

Ribosomes serve as the site of protein synthesis where messenger RNA (mRNA) is translated into a polypeptide chain, facilitating the assembly of amino acids according to the sequence coded by the mRNA.

What is the significance of the genetic code in gene expression?

The genetic code is a set of rules that dictate how sequences of nucleotides in DNA and RNA are translated into amino acids. It is crucial for ensuring that proteins are synthesized correctly, which affects the functioning of all living organisms.

What are the steps involved in transcription as outlined in Chapter 17?

Transcription involves three main steps: initiation, where RNA polymerase binds to the promoter; elongation, where RNA polymerase synthesizes the RNA strand; and termination, where the RNA polymerase reaches a terminator sequence and releases the newly formed RNA.

How does post-transcriptional modification affect mRNA before it is translated?

Post-transcriptional modifications, such as the addition of a 5' cap, a poly-A tail, and splicing out of introns, help stabilize mRNA, facilitate its export from the nucleus, and ensure that only the coding sequences (exons) are translated into proteins.
