Fundamentals of Chemical Thermodynamics

Basic Principles

Chemical thermodynamics deals with the relationships between heat, work, and chemical reactions. The following principles serve as the foundation for understanding this field:

1. First Law of Thermodynamics: This law states that energy cannot be created or destroyed, only transformed from one form to another. In mathematical terms, it can be expressed as:
$$
\Delta U = Q - W
$$
where ΔU is the change in internal energy, Q is the heat added to the system, and W is the work done by the system.

2. Second Law of Thermodynamics: This law introduces the concept of entropy, stating that the total entropy of an isolated system can never decrease over time. It emphasizes the direction of spontaneous processes and the irreversibility of natural phenomena.

3. Gibbs Free Energy: The Gibbs free energy (G) is a crucial quantity that helps predict the spontaneity of reactions at constant temperature and pressure. The relationship is given by:
$$
G = H - TS
$$
where H is enthalpy, T is temperature, and S is entropy.

Thermodynamic Properties

Understanding thermodynamic properties is essential for applying the laws of thermodynamics to real-world problems. Key properties include:

- Enthalpy (H): A measure of the total heat content of a system, defined as $H = U + PV$, where P is pressure and V is volume.
- Entropy (S): A measure of the disorder or randomness in a system, crucial for understanding the feasibility of processes.
- Internal Energy (U): The total energy contained within a system, including kinetic and potential energy at the molecular level.
- Specific Heat: The amount of heat required to change the temperature of a unit mass of a substance by one degree Celsius.

Common Problems and Solutions

Example Problems from Koretsky's Solutions

Koretsky's textbook provides numerous example problems that illustrate the application of thermodynamic principles. Here are a few common problem types along with their solutions:

1. Calculating Work Done in a Process:

- Problem: A gas expands isothermally from an initial volume of 1 L to a final volume of 4 L at a temperature of 300 K. Calculate the work done by the gas.
- Solution: The work done during isothermal expansion can be calculated using the formula:
$$
W = nRT \ln\left(\frac{V_f}{V_i}\right)
$$
where n is the number of moles, R is the universal gas constant, T is the temperature, V_f is the final volume, and V_i is the initial volume.

2. Finding Changes in Enthalpy:
- Problem: For a reaction where 2 moles of A react to form 3 moles of B, with the enthalpy change given as $\Delta H = -100 kJ$. Calculate the enthalpy change per mole of A.
- Solution: The enthalpy change per mole of A can be calculated by dividing the total change by the number of moles of A:
$$
\Delta H_{\text{per mole of A}} = \frac{-100 \, \text{kJ}}{2} = -50 \, \text{kJ/mol}
$$

3. Phase Equilibrium Calculations:
- Problem: Determine the equilibrium vapor pressure of a substance at a given temperature using the Clausius-Clapeyron equation.
- Solution: The Clausius-Clapeyron equation relates the change in vapor pressure with temperature:
$$
\ln\left(\frac{P_2}{P_1}\right) = -\frac{\Delta H_{vap}}{R}\left(\frac{1}{T_2} - \frac{1}{T_1}\right)
$$
where ΔH_{vap} is the enthalpy of vaporization, R is the gas constant, and P_1 and P_2 are the vapor pressures at temperatures T_1 and T_2 respectively.
