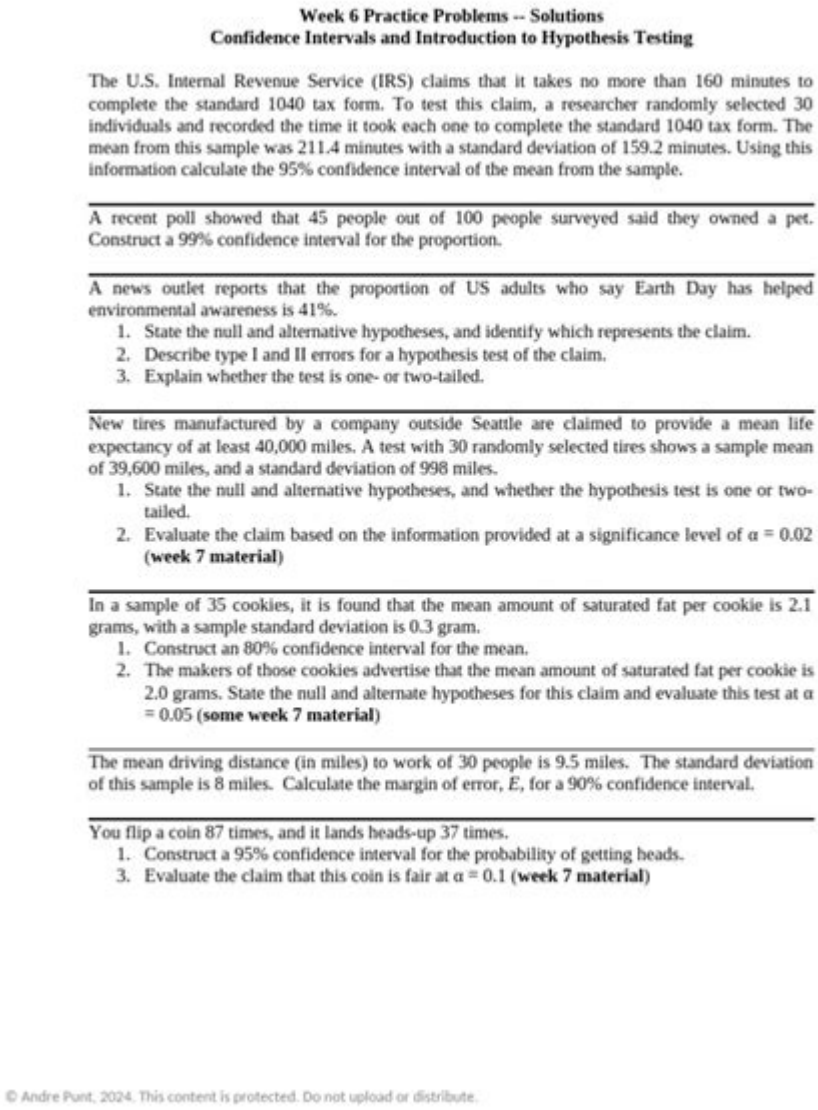
Null Hypothesis Practice Problems



Week 6 Practice Problems -- Solutions
Confidence Intervals and Introduction to Hypothesis Testing

The U.S. Internal Revenue Service (IRS) claims that it takes no more than 160 minutes to complete the standard 1040 tax form. To test this claim, a researcher randomly selected 30 individuals and recorded the time it took each one to complete the standard 1040 tax form. The mean from this sample was 211.4 minutes with a standard deviation of 159.2 minutes. Using this information calculate the 95% confidence interval of the mean from the sample.

A recent poll showed that 45 people out of 100 people surveyed said they owned a pet. Construct a 99% confidence interval for the proportion.

A news outlet reports that the proportion of US adults who say Earth Day has helped environmental awareness is 41%.

1. State the null and alternative hypotheses, and identify which represents the claim.
2. Describe type I and II errors for a hypothesis test of the claim.
3. Explain whether the test is one- or two-tailed.

New tires manufactured by a company outside Seattle are claimed to provide a mean life expectancy of at least 40,000 miles. A test with 30 randomly selected tires shows a sample mean of 39,600 miles, and a standard deviation of 998 miles.

1. State the null and alternative hypotheses, and whether the hypothesis test is one or two-tailed.
2. Evaluate the claim based on the information provided at a significance level of $\alpha = 0.02$ (**week 7 material**)

In a sample of 35 cookies, it is found that the mean amount of saturated fat per cookie is 2.1 grams, with a sample standard deviation is 0.3 gram.

1. Construct an 80% confidence interval for the mean.
2. The makers of those cookies advertise that the mean amount of saturated fat per cookie is 2.0 grams. State the null and alternate hypotheses for this claim and evaluate this test at $\alpha = 0.05$ (**some week 7 material**)

The mean driving distance (in miles) to work of 30 people is 9.5 miles. The standard deviation of this sample is 8 miles. Calculate the margin of error, E, for a 90% confidence interval.

You flip a coin 87 times, and it lands heads-up 37 times.

1. Construct a 95% confidence interval for the probability of getting heads.
3. Evaluate the claim that this coin is fair at $\alpha = 0.1$ (**week 7 material**)

Null hypothesis practice problems are an essential component of statistical analysis, particularly in the field of hypothesis testing. Understanding how to formulate, test, and interpret null hypotheses is crucial for researchers across various disciplines, including psychology, medicine, and economics. This article provides an in-depth look at null hypothesis practice problems, the steps involved in hypothesis testing, and some practical examples to help solidify this fundamental concept in statistics.

Understanding the Null Hypothesis

The null hypothesis, often denoted as H0, is a statement that indicates no effect or no difference in a given situation. It serves as a benchmark against which an alternative hypothesis (H1) is tested. The

primary objective of hypothesis testing is to gather evidence to reject the null hypothesis in favor of the alternative hypothesis.

Key Characteristics of the Null Hypothesis

1. Testable Statement: The null hypothesis must be a statement that can be tested using statistical methods.
2. Assumes No Effect: H0 typically suggests that any observed effect in the data is due to random chance.
3. Basis for Statistical Testing: It provides a framework for deciding whether to accept or reject a hypothesis based on sample data.

The Hypothesis Testing Process

The process of hypothesis testing involves several systematic steps:

1. **Formulate Hypotheses**: Identify the null hypothesis (H0) and the alternative hypothesis (H1).
2. **Select Significance Level**: Choose a significance level (α), commonly set at 0.05, which indicates a 5% risk of concluding that an effect exists when there is none.
3. **Collect Data**: Gather sample data relevant to the hypotheses being tested.
4. **Conduct Statistical Test**: Use an appropriate statistical test (e.g., t-test, chi-square test) to analyze the data.
5. **Make a Decision**: Based on the test results, determine whether to reject or fail to reject the null hypothesis.
6. **Draw Conclusions**: Interpret the results in the context of the research question.

Practice Problems for Null Hypothesis Testing

To effectively understand null hypothesis testing, practicing with real-world problems is beneficial. Below are several practice problems along with their solutions.

Problem 1: Testing a New Drug

A pharmaceutical company claims that a new drug reduces blood pressure more effectively than the current standard. A study is conducted where 100 patients are given the new drug, and their blood

pressure is measured. The standard drug reduces blood pressure by an average of 5 mmHg with a standard deviation of 1.5 mmHg.

1. Formulate the Hypotheses:
- H0: The new drug has no effect on blood pressure reduction ($\mu = 5$ mmHg).
- H1: The new drug reduces blood pressure more than the standard ($\mu > 5$ mmHg).

2. Significance Level: Set $\alpha = 0.05$.

3. Collect Data: Suppose the new drug results in an average reduction of 6 mmHg with a standard deviation of 1.2 mmHg.

4. Conduct Statistical Test:
- Use a one-sample t-test to compare the means.

5. Make a Decision: Calculate the t-statistic and compare it to the critical t-value from the t-distribution table.

6. Draw Conclusions: If the t-statistic exceeds the critical value, reject H0, suggesting the new drug is more effective.

Problem 2: Effect of Training on Test Scores

A school implements a new training program and wants to determine if it significantly improves student test scores compared to the previous average score of 75%.

1. Formulate the Hypotheses:
- H0: The training program has no effect on test scores ($\mu = 75\%$).
- H1: The training program improves test scores ($\mu > 75\%$).

2. Significance Level: Set $\alpha = 0.01$.

3. Collect Data: After the training, a sample of 30 students has an average score of 78% with a standard deviation of 5%.

4. Conduct Statistical Test:
- Perform a one-sample t-test.

5. Make a Decision: Compare the calculated t-statistic with the critical value at df = 29.

6. Draw Conclusions: If H0 is rejected, it indicates the training program has had a significant impact.

Problem 3: Marketing Strategy Evaluation

A company wants to test whether a new marketing strategy increases sales compared to the previous average monthly sales of $20,000.

1. Formulate the Hypotheses:
- H0: The new marketing strategy does not increase sales ($\mu = \$20,000$).
- H1: The new marketing strategy increases sales ($\mu > \$20,000$).

2. Significance Level: Set $\alpha = 0.05$.

3. Collect Data: After implementing the new strategy, data from 50 months shows an average sale of $22,000 with a standard deviation of $4,000.

4. Conduct Statistical Test:
- Use a one-sample t-test.

5. Make a Decision: Analyze the t-statistic against the critical value.

6. Draw Conclusions: If H0 is rejected, the new strategy is deemed effective.

Common Errors in Null Hypothesis Testing

When practicing null hypothesis testing, researchers often encounter common pitfalls:

- **Misinterpretation of p-values**: A p-value less than the significance level indicates rejection of H0, not the probability that H0 is true.
- **Overreliance on statistical significance**: A statistically significant result does not equate to practical significance.
- **Ignoring Type I and Type II errors**: Type I error occurs when H0 is wrongly rejected, while Type II error occurs when H0 is not rejected when it is false.

Conclusion

Null hypothesis practice problems are vital for developing a solid foundation in statistical hypothesis testing. By understanding the formulation, testing, and interpretation of null hypotheses through practical examples, researchers can enhance their analytical skills and make informed decisions based on statistical data. As with any statistical method, continuous practice and careful attention to detail are key to mastering hypothesis testing.

Frequently Asked Questions

What is a null hypothesis in statistical testing?

A null hypothesis is a statement that there is no effect or no difference, and it serves as the starting point for statistical testing. It is often denoted as H0.

How do you formulate a null hypothesis for a study comparing two groups?

To formulate a null hypothesis for comparing two groups, you would state that the means of the two groups are equal. For example, H0: μ1 = μ2, where μ1 and μ2 are the population means of the two groups.

What are some common mistakes when practicing null hypothesis problems?

Common mistakes include misinterpreting the null hypothesis, failing to specify the alternative hypothesis, and confusing statistical significance with practical significance.

What is the significance level in the context of a null hypothesis?

The significance level, often denoted as alpha (α), is the threshold for rejecting the null hypothesis. A common alpha level is 0.05, indicating a 5% risk of concluding that an effect exists when there is none.

How do you determine whether to reject or fail to reject the null hypothesis?

You determine whether to reject or fail to reject the null hypothesis by comparing the p-value obtained from your statistical test to the significance level. If the p-value is less than α, you reject the null hypothesis.

Can you provide an example of a null hypothesis practice problem?

Sure! Suppose you want to test if a new teaching method affects student performance. You can set the null hypothesis as H0: There is no difference in average test scores between students taught with the new method and those taught with the traditional method.

What is the role of the alternative hypothesis in null hypothesis testing?

The alternative hypothesis (H1) represents what you want to prove and is the statement that there is an effect or a difference. It is what you conclude if you reject the null hypothesis.
