## Understanding the Menstrual Cycle

The menstrual cycle is a natural process that occurs in individuals with a

uterus, primarily influenced by hormonal changes. It typically lasts about 28 days, although variations are common. Understanding the menstrual cycle is crucial for various reasons, including reproductive health, awareness of fertility, and recognizing signs of potential health issues.

## **Phases of the Menstrual Cycle**

The menstrual cycle can be divided into several distinct phases, each characterized by specific hormonal changes and physical effects. These phases include:

### **1. Menstrual Phase (Days 1-5)**

- The cycle begins with menstruation, where the uterine lining sheds.
- This phase usually lasts 3 to 7 days.
- Hormone levels, particularly estrogen and progesterone, are at their lowest.

### **2. Follicular Phase (Days 1-13)**

- Overlaps with the menstrual phase.
- The pituitary gland releases Follicle Stimulating Hormone (FSH), promoting follicle development.
- Estrogen levels begin to rise, leading to the thickening of the uterine lining.

### **3. Ovulation (Day 14)**

- Triggered by a surge in Luteinizing Hormone (LH).
- The mature follicle releases an egg, which is the most fertile period.
- Typically occurs around the midpoint of the cycle.

### **4. Luteal Phase (Days 15-28)**

- After ovulation, the ruptured follicle transforms into the corpus luteum.
- Progesterone levels rise, maintaining the uterine lining for potential implantation.
- If fertilization does not occur, hormone levels drop, leading back to menstruation.
